

DESCRIPTION OF *ENNEA AFFECTATA*, n.sp., FROM ZANZIBAR.

By HUGO FULTON.

Read 13th December, 1901.

ENNEA AFFECTATA, n.sp.

Shell sub-cylindrical, rimate, opaque white, sculptured with oblique, raised striæ; whorls $7\frac{3}{4}$, barely convex, slowly increasing, first four tapering from a rather obtuse apex, back of last whorl constricted by two folds; aperture with a prominent, somewhat short, parietal plait, a little distance from the right margin of the peristome, two parallel basal laminae far within, the left-hand one only just visible from the exterior, at a half-whorl from the peristome there is another parietal (spiral) plait, and the columella is pressed out into a broad tooth-like projection extending half-way across the opening; peristome slightly expanded, margins joined by a thin callus. Diam. maj. 6.5, alt. 13.5 mm.

*Ennea affectata*, n.sp.*Hab.*—Zanzibar.

This species is quite distinct from any other of the genus known to me. *Ennea trigonostoma*, Marts., is somewhat similar in its general characters, but is larger, not so cylindrical, and its basal plaits are placed quite forward, not far back within the interior as in *E. affectata*.
